## 2. Scientific Objectives

Goal: Develop and apply tools to models of multivariate heavy tail phenomena:

- applied probability modeling,
- statistical modeling, simulation, numerical analysis.
- control and optimization; algorithms.

Synthesize core discipline strengths:

applied probability, statistics, simulation, numerical analysis, computer science, electrical engineering, operations research and optimization.

Apply to significant application areas:

- risk estimation,
- social networks,
- cloud computing,
- scheduling and control, eg cloud computing,
- anomaly detection.

## 3. Heavy Tailed Phenomena

### 3.1. Description?

- Rough: The probability of observing **large** multivariate values is **relatively** large.

**Large** usually means beyond the range of the data.

- Associated with *power laws*: In one dimension, if  $X > 0$ , roughly

$$P[X > x] \approx x^{-\alpha}, \quad x > x_0.$$

- Need to specify a dependence structure; correlations may not exist and are vague information.

- Generalize to higher dimensions  $d$  or even sequence or stochastic processes. If  $\mathbf{X} = (X_1, \dots, X_d) \in \mathbb{R}_+^d$ ,  $\mathbf{X}$  has a multivariate heavy tail if

- $\exists b(t) \rightarrow \infty$  as  $t \rightarrow \infty$ , and
- $\exists$  measure  $\nu(\cdot)$ , such that for nice sets  $A$  (thought of as *tail regions*,

$$tP\left[\frac{\mathbf{X}}{b(t)} \in A\right] \rightarrow \nu(A). \quad (\text{HT})$$

- To infer beyond the range of the data, we make the reasonably robust assumption that (HT) holds so that for tail region  $\mathcal{R}$ ,

$$P[\mathbf{X} \in \mathcal{R}] \approx \frac{1}{t}\nu(\mathcal{R}/b(t)) \approx \frac{1}{t}\hat{\nu}(\mathcal{R}/\hat{b}(t)).$$

Replacement of a converging family by the limit is *peaks over threshold* (POT) philosophy.

- Estimates based on asymptotic methods depend on a convergence rate as a threshold gets large.
- There could be more than one relevant asymptotic regime. Ouch!

## 3.2. How to model different dependence structures in heavy tailed data

- (Left) Large values occur together (strong extremal dependence)
- (Middle) Large value of one variable occurs with range of values in other.
- (Right) No risk contagion or extremal dependence.

## 4. Model Generation

### 4.1. A general construction of a standardized multivariate heavy tailed distribution

- On  $\mathbb{R}_+^d$ , delete a closed cone  $F$ ; for example:
  - $F = \{\mathbf{0}\}$  or
  - $F = [\text{axes}]$ .
- Regions away from  $F$  are considered *tail regions*.
- Write

$$\mathfrak{N}_F = \{\mathbf{x} : d(\mathbf{x}, F) = 1\}.$$

Take

$\Theta$  random element in  $\mathfrak{N}_F$ ,  $R \sim \text{Pareto}$ ,  $\Theta \perp R$ .

- Set

$$\mathbf{X} = R\Theta$$

and  $\mathbf{X} \in \text{MRV}$  on  $\mathbb{R}_+^d \setminus F$ .

Can apply this construction to successive choices of deleted  $F$ :

Team

Objective

Heavy Tails

Generation

Detection

Challenges

Title Page

Page 7 of 22

Go Back

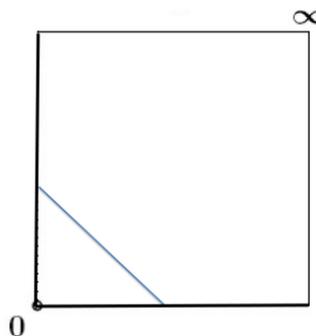

Full Screen

Close

Quit

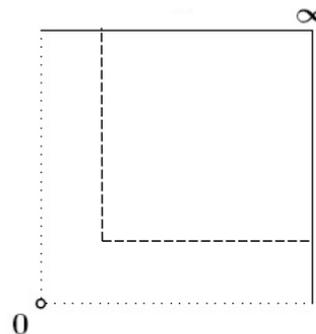

- first delete  $F_1$  (eg, origin)

- $\aleph_0 = [\|\mathbf{x}\| = 1]$
- tail regions bounded away from  $\mathbf{0}$ .
- $tP[\mathbf{X}/b(t) \in A] \rightarrow \nu(A)$  for  $A$  bounded away from  $\mathbf{0}$ .

- then deleting  $F_1 \cup F_2$ ;  
ie, delete 2nd cone  $F_2$  (eg, axes).

- $\aleph_{[\text{axes}]}$  = dashed lines.
- tail regions bounded away from axes; both components big
- $tP[\mathbf{X}/b_1(t) \in A] \rightarrow \nu_1(A)$  for  $A$  bounded away axes.

## 4.2. Hidden regular variation

When  $\mathbf{X}$  has regular variation on both  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$  and  $\mathbb{R}_+^2 \setminus [\text{axes}]$ , and

$$b(t)/b_1(t) \rightarrow \infty,$$

we say  $\mathbf{X}$  has **hidden regular variation (HRV)**.

? How do the 2 regular variation properties interact? Statistically identifiable? [Das and Resnick \(2014\)](#).

#### 4.2.1. Methods to generate models having both MRV & HRV:

- Product method described above:
  - Construct  $R\Theta$ , MRV on  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$ .
  - Moment conditions ensure  $R\Theta_i$  are one-dimensional regularly varying.
  - Once marginals are regularly varying,  $R\Theta$  has a multivariate distribution that is also regularly varying on  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$ .
- Mixture method (Maulik and Resnick, 2005).

$$\mathbf{X} = B\mathbf{Y} + (1 - B)\mathbf{V}, \quad B \perp \mathbf{Y} \perp \mathbf{V},$$

where

- $B$  is a Bernoulli switching variable:  $P[B = 0] = P[B = 1] = 1/2$ .
- $\mathbf{Y}$  is regularly varying on  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$ .
- $\mathbf{V}$  is regularly varying on  $\mathbb{R}_+^2 \setminus \{\text{[axes]}\}$ .

Quit

- Additive models (Weller and Cooley, 2014):

$$\mathbf{X} = \mathbf{Y} + \mathbf{V}, \quad \mathbf{Y} \perp \mathbf{V},$$

where

- $\mathbf{Y}$  is MRV on  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$
- $\mathbf{V}$  is MRV on  $\mathbb{R}_+^2 \setminus \{[\text{axes}]\}$ .

This model has severe identification issues:

- Does HRV of  $\mathbf{X}$  come from  $\mathbf{Y}$  (sometimes) or  $\mathbf{V}$  (sometimes)?
- Is the hidden index of regular variation of  $\mathbf{X}$  (the scaling property) what one would predict from  $\mathbf{V}$  (not necessarily).

## 5. Model Detection Diagnostics

When should MRV or HRV be applied to data?

1. Reduction to one dimension:

- $\mathbf{X} \in \text{MRV}$  on  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$  iff  $aX_1 \vee bX_2 \in RV(\alpha)$  for all  $a \geq 0, b \geq 0$ .
- $\mathbf{X} \in \text{HRV}$  on  $\mathbb{R}_+^2 \setminus [\text{axes}]$  iff  $aX_1 \wedge bX_2 \in RV(\alpha_0)$  for  $a \wedge b > 0$ .

[Hint: Cannot check  $\forall a, b$ .]

2. Use GPOLAR to convert to the CEV model and then use CEV diagnostics (Das and Resnick, 2011) using the *Hillish* and *Pickandish* plots.

- A CEV model for  $(\xi, \eta)$  has the form

$$tP \left[ \left( \frac{\xi}{b(t)}, \eta \right) \in \cdot \right] \rightarrow \mu(\cdot),$$

on  $(0, \infty) \times [0, \infty)$ .

- MRV on  $\mathbb{R}_+^2 \setminus \{0\}$ , after transformation via GPOLAR is of the form

$$tP\left[\underbrace{(\|\mathbf{X}\|/b(t))}_{\xi}, \underbrace{(\mathbf{X}/\|\mathbf{X}\|)}_{\eta} \in \cdot\right] \rightarrow \underbrace{\nu_\alpha \times S(\cdot)}_{\text{product measure}}, \quad \text{on } (0, \infty) \times \mathcal{N}_0.$$

- HRV on  $\mathbb{R}_+^2 \setminus [\text{axes}]$  after transformation by

$$\text{GPOLAR} : \mathbf{x} \mapsto \left( d(\mathbf{x}, \mathcal{N}_{[\text{axes}]}) , \frac{\mathbf{x}}{d(\mathbf{x}, \mathcal{N}_{[\text{axes}]})} \right),$$

is of the form

$$tP\left[\left(\frac{X_1 \wedge X_2}{b_0(t)}, \frac{\mathbf{X}}{X_1 \wedge X_2}\right) \in \cdot\right] \rightarrow \nu_{\alpha_0} \times S_0(\cdot) \quad \text{on } ((0, \infty) \times \mathcal{N}_{[\text{axes}]}) .$$

## 5.0.2. Hillish statistic.

Suppose  $(\xi_i, \eta_i); 1 \leq i \leq n$  are iid samples in  $\mathbb{R}_+^2$  and  $(\xi_1, \eta_1) \in \text{CEV}(b, \mu)$ . Notation:

$\xi_{(1)} \geq \dots \geq \xi_{(n)}$  The decreasing order statistics of  $\xi_1, \dots, \xi_n$ .

$\eta_i^*, 1 \leq i \leq n$  The  $\eta$ -variable corresponding to  $\xi_{(i)}$ , also called the concomitant of  $\xi_{(i)}$ .

$N_i^k = \sum_{l=i}^k \mathbf{1}_{\{\eta_l^* \leq \eta_i^*\}}$  Rank of  $\eta_i^*$  among  $\eta_1^*, \dots, \eta_k^*$ . We write  $N_i = N_i^k$ .

**Hillish statistic.** For  $1 \leq k \leq n$ , the *Hillish statistic* is

$$\text{Hillish}_{k,n} = \text{Hillish}_{k,n}(\xi, \eta) := \frac{1}{k} \sum_{j=1}^k \log \frac{k}{j} \log \frac{k}{N_j^k} \quad (1)$$

Properties (Das and Resnick, 2011): If,

- $(\xi_i, \eta_i); 1 \leq i \leq n$  are iid observations from the  $\text{CEV}(b, \mu)$ ;
- Mild regularity.
- $k = k(n) \rightarrow \infty, n \rightarrow \infty$  and  $k/n \rightarrow 0$ .

then

$$\text{Hillish}_{k,n} \xrightarrow{P} I_\mu = \text{ugly integral.}$$

Moreover  $\mu$  is a product measure if and only if both

$$\text{Hillish}_{k,n}(\xi, \eta) \xrightarrow{P} 1 \quad \text{and} \quad \text{Hillish}_{k,n}(\xi, -\eta) \xrightarrow{P} 1.$$

Usefulness: Detect either MRV or HRV after applying GPOLAR.

### 5.0.3. Example: BU data; HTTP downloads: MRV with asymptotic independence + HRV

- HTTP downloads in sessions from 1995.
- 8 hours 20 minutes worth of downloads after applying an aggregation rule to downloads to associate machine triggered actions with human requests. See [Guerin, Nyberg, Perrin, Resnick, Rootzén, and Stărică \(2003\)](#).
- 4161 downloads.

Consider the variables:

- $S$  = the size of the download in kilobytes,
- $D$  = the duration of the download in seconds,
- $R$  = throughput of the download; that is,  $= S/D$ .

Concentrate on  $(D, R)$  and *standardize* with rank transformed variables:

$$D_i^* = \sum_{j=1}^{4161} \mathbf{1}_{\{D_i \geq D_j\}}, R_i^* = \sum_{j=1}^{4161} \mathbf{1}_{\{R_i \geq R_j\}}.$$

Duration

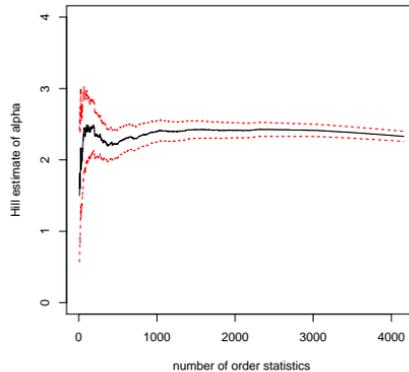

Rate

angular density for Duration\* vs. Rate\*

min(Duration\*, Rate\*)

## Conclusions so far:

- Hill plots for marginals  $D^*$  and  $R^*$  consistent with marginal heavy tails.
- Evidence that the MRV on  $\mathbb{R}_+^2 \setminus \{\mathbf{0}\}$  exists with asymptotic independence and limit measure concentrates on [axes]:
  - Spectral density plot seems to concentrate on  $\{0\}$  and  $\{\pi/2\}$ .
  - Hill plot for  $\min(D^*, R^*)$  is heavy tailed but with index

$$\alpha_0 \approx 2.4 > 1 = \text{marginal indices}$$

which is evidence for regular variation on  $\mathbb{R}_+^2 \setminus \{\text{[axes]}\}$ .

- Will Hillish confirm existence of HRV on  $\mathbb{R}_+^2 \setminus \{\text{[axes]}\}$ ?

## 6. Challenges.

- Practical?
  - Limitations of asymptotic methods: rates of convergence?
- Need for more formal inference for estimation including confidence statements.
- General HRV technique in higher dimensions requires knowing the support of the limit measure. Estimate support?
- High dimension problems? How to sift through different possible subcones? There could be a sequence of cones with regular variation on each. How to teach a computer to find the cones?
- How to go from standard to more realistic non-standard case; still some inference problems.
